

CERN community: Join our spring scavenger hunt to win chocolate

Celebrate the start of spring by exploring CERN's biodiversity online, with the chance to win two CAGI Choco Passes

(Image: S. Fenkart/CERN)

Spring is in the air! As the [accelerator complex](#) starts to awaken, so too does the biodiversity on the CERN site. But it's not just [blossom on the trees](#) and [sheep](#) returning to graze – the vast CERN sites are home to a plethora of species.

To celebrate spring, we're launching an **online nature-themed scavenger hunt**, using the ["biodiversity walk" website](#). Created by SCE's [Geographic Information System](#) team, the biodiversity walk takes you on a comprehensive virtual tour of CERN's biodiversity around Meyrin, Prévessin and beyond.

Participants in the scavenger hunt will have a chance to win two [CAGI Choco Passes](#) courtesy of Geneva Tourism and the International Geneva Welcome Centre (CAGI), which runs a [cultural kiosk](#) at CERN. The Choco Passes are for two people to spend a day exploring Geneva and sampling chocolates from a range of different chocolate shops.

CERN mobility: driven by data, naturally

Particle physics is all about data, and so too is mobility at CERN. Over the years, our travel habits have been changing, and more changes are to come

Particle physics is all about data, but so too is mobility at CERN. The data shows that we feel strongly about how we get to work and how we get around the CERN sites – on foot, by car, bike, shuttle and more. We see this in the large number of responses to CERN mobility surveys over the last decade. Interesting trends are emerging, and the Site and Civil Engineering (SCE) department is responding to them within CERN and in collaboration with our Host States.

Mobility masterplan

CERN's first CERN mobility survey was conducted in 2014 following a request by Geneva's [Office cantonal des transports \(OCT\)](#) that Geneva-based international organisations survey their populations about travel habits. This led to a joint mobility plan, drawn up between international organisations, the State of Geneva and the Swiss Mission, which included raising awareness about mobility issues. The launch of CERN's first mobility survey marked the beginning of the mobility adventure and of concrete plans to improve parking management, communication and infrastructure.

[CERN's mobility plan](#) was updated in 2024 to include action on motorised transportation, alternative mobility and accessibility, with a strong focus on sustainability. For the many new initiatives, SCE has taken the particle physics approach: we conduct a pilot, we test and analyse data, and then we go with the best solution. This has seen us step up efforts to support soft mobility across the CERN sites: increasing the bike fleet to 600, gradually installing more bike shelters, setting up bike repair points and charging points for e-bikes, and many more as explained in detail at the recent [SCE seminar](#).

Host State collaboration

Our mobility plan has also seen CERN work closely with the French and Swiss authorities to improve mobility in the areas surrounding the CERN sites. CERN played a decisive role in the planning and

construction of the Route de l'Europe cycle path linking the Meyrin and Préveessin sites. Improvements to cycle paths around Meyrin Entrance A and the Préveessin entrance are under development and are expected later this year. Public transport has continued to be reinforced over the years, with more frequent buses and trams. This is set to continue to improve in the years to come.

Mobility changes: comparing survey data from 2017 and 2023 shows an 8% increase in bicycle use and a 6% reduction in single-occupancy cars. (Image: CERN)

Sustainable transport

In September 2025, the SCE department will be launching a Mobility Week for the CERN community with the aim of encouraging alternative, sustainable transport through challenges, games and prizes (more details to come).

In the meantime, mobility survey data shows that bicycle use at CERN increased by 8% between 2017

and [2023](#). With spring now beginning and thousands of bicycle parking spaces available across the CERN sites, it's time to get ready for [this year's Bike2Work challenge](#) in May and June – let's see if we can beat [last year's records](#).

Mar Capeans

Head of the Site and Civil Engineering department

>>> Continued from page 1

Here's how to enter the scavenger hunt:

- Open the biodiversity walk website at cern.ch/biodiversity-walk.
- Use the information you find there to answer the questions below.
- Send your answers to bulletin-editors@cern.ch by **Monday, 14 April, 11.59 p.m. CEST** from your CERN email address.

All entries will go into a prize draw and the winner of the two Choco Passes will be announced in the next edition of the Bulletin. **Good luck!**

Questions:

1. Eighteen species of which type of plant can be found across the CERN sites?
2. Which snake can be seen slithering near LHC Point 6? No need to worry, it is harmless and, if threatened, will play dead.
3. Which species has yellow translucent wings and can be found near Crozet? It is not a dragonfly, even if it may look like one.
4. Which bird, found on the Prévessin site, has the impressive multitasking skills of eating, sleeping and even mating in mid-flight?
5. Which common bird sings alongside a beautiful experiment?

Internal Communication

Accelerator Report: The LHC commissioning is well on track, but challenges lie ahead

The first beam-based physics of 2025 has started and more will follow soon. However, some unexpected challenges will cause a small delay in the restart of the LHC

Last week, on 19 March, the first beam-based physics of the year began when protons from the PS hit the n_TOF target, producing the neutrons required for the n_TOF experiments. On that same day, physics was also scheduled to start in the PS East Area, but had to be delayed after an issue with a collimator in one of the four East Area beamlines was identified: the collimator was found to be partially closed and obstructing the beam path.

Collimators are key components used to remove unwanted halo particles from the beam. They consist of movable parts that can be adjusted electro-mechanically to set the beam's aperture. In this case, the faulty collimator required replacement.

Under the coordination of the Experimental Areas (BE-EA) group, a team of experts from various domains quickly devised a plan for the replacement. However, accessing the collimator required the removal of the thick concrete shielding blocks above the beamline.

Initial estimates projected a delay of three to four days to the start of physics in the East Area, with hopes of resuming beam operations over the weekend. Thanks to the efficiency and excellent collaboration of the teams involved, the collimator was successfully replaced and the shielding reinstated in the early afternoon of 22 March. Beam for physics was delivered to the East Area at 4 p.m. that same day, just in time for the weekend and only two days behind the original schedule.

On the left: the collimator that has been replaced. On the right: work in progress to remove the roof shielding to access the collimator. (Image: G. Romagnoli (BE-EA))

Meanwhile, beam commissioning in the SPS is progressing well. A high-intensity LHC-type beam, containing more protons per bunch than usual, is currently being used to “scrub” the vacuum chamber. This [scrubbing process](#) helps reduce the emission of secondary electrons, which in turn lowers the formation of electron clouds. Minimising electron-cloud effects is essential for stable beam conditions and quality when the LHC-type beam is eventually delivered to the LHC.

In parallel, SPS experts have been setting up the beam and its slow extraction for the SPS North Area. Slow extraction is a technique in which the accelerated beam is gradually extracted from the SPS over millions of turns. During each turn, only a small fraction of the beam is extracted, allowing the entire extraction process to span approximately 4.5 seconds.

In the coming weeks, beamline physicists will use this extracted beam to set up the various beamlines in the North Area, delivering the beam to the experiments. Physics in the North Area is scheduled to begin on 14 April.

In [my previous report](#), I mentioned the presence of a small vacuum leak in the SPS. The opening and closing of this leak appear to be synchronised with the pulsing of the magnets, but the leak remains too small to be precisely located, making it impossible to determine with certainty which magnet needs to be replaced.

Depending on how one looks at it, the leak has fortunately or unfortunately not evolved; it remains present but stable. As time goes on, however, it is increasingly likely that a one-day stop during the physics run may be required to replace a magnet. That said, this decision will depend on whether the leak worsens and becomes easier to localise. We continue to monitor the situation closely and will keep you informed as it develops.

On the LHC side, testing of all power converters, electrical circuits, magnets and other systems is progressing well and is even slightly ahead of schedule. On the machine side all remains on track for the first beam injection, originally planned for 4 April.

However, we recently received some unfortunate news from the ATLAS experiment. A water leak was discovered in the cooling system of their argon calorimeter (detector), which now requires repair. To access the affected components, the detector must be opened on one side, which is usually a complex and time-consuming operation. Despite the complexity of the operation, the resulting delay to the overall LHC schedule is expected to be limited to just two weeks. This situation highlights a key difference between the LHC and the rest of the accelerator complex: in the LHC, the experiments are fully integrated into the machine itself, meaning that an intervention in

ATLAS directly affects the ability to inject and circulate beam. In contrast, experiments in the injector complex operate on separate beamlines and are therefore independent of accelerator operation.

The LHC machine teams are working closely with the ATLAS collaboration to develop a plan that makes most efficient use of the available time and keeps the delay to a minimum.

Originally, first beam was scheduled for 4 April, comfortably ahead of the Easter weekend. Many were pleased, as LHC beam commissioning has traditionally, though unintentionally, coincided with Easter. Now, if the two-week delay holds, the 2025 commissioning may once again fall during the Easter weekend. Have we discovered a new constant of nature? We'll see in the coming days when the details become clearer...

Rende Steerenberg

A new piece in the matter–antimatter puzzle

The LHCb experiment at CERN has revealed a fundamental asymmetry in the behaviour of particles called baryons

View of the LHCb experiment in its underground cavern (Image: CERN)

Yesterday, at the annual [Rencontres de Moriond](#) conference taking place in La Thuile, Italy, the [LHCb](#) collaboration at CERN reported a new milestone in our understanding of the subtle yet profound differences between matter and antimatter. In its [analysis](#) of large quantities of data produced by the Large Hadron Collider ([LHC](#)), the international team found overwhelming

evidence that particles known as baryons, such as the protons and neutrons that make up atomic nuclei, are subject to a mirror-like asymmetry in nature's fundamental laws that causes matter and antimatter to behave differently. The discovery provides new ways to address why the elementary particles that make up matter fall into the neat patterns described by the Standard Model of particle physics, and to explore why matter apparently prevailed over antimatter after the Big Bang.

First observed in the 1960s among a class of particles called mesons, which are made up of a quark–antiquark pair, the violation of “charge–parity (CP)” symmetry has been the subject of intense study at both fixed-target and collider experiments. While it was expected that the other main class of known particles – baryons, which are made up of three quarks – would also be subject to this phenomenon, experiments such as LHCb had only seen hints of CP violation in baryons until now.

“The reason why it took longer to observe CP violation in baryons than in mesons is down to the size of the effect and the available data,” explains LHCb spokesperson Vincenzo Vagnoni. “We needed a machine like the LHC capable of producing a large enough number of beauty baryons and their antimatter counterparts, and we needed an experiment at that machine capable of pinpointing their decay products. It took over 80 000 baryon decays for us to see matter–antimatter asymmetry with this class of particles for the first time.”

Particles are known to have identical mass and opposite charges with respect to their antimatter partners. However, when particles transform or decay into other particles, for example as occurs when an atomic nucleus undergoes radioactive decay, CP violation causes a crack in this mirror-like symmetry. The effect can manifest itself in a difference between the rates at which particles and their antimatter counterparts decay into lighter particles, which physicists can log using highly sophisticated detectors and data analysis techniques.

The LHCb collaboration observed CP violation in a heavier, short-lived cousin of protons and neutrons called the beauty-lambda baryon Λ_b , which is composed of an up quark, a down quark and a beauty quark. First, they sifted through data collected by the LHCb detector during the first and second runs of the LHC (which lasted from 2009 to 2013 and from 2015 to 2018, respectively) in search of the decay of the Λ_b particle into a proton, a kaon and a pair of oppositely charged pions, as well as the corresponding decay of its antimatter counterpart, the anti- Λ_b . They then counted the numbers of the observed decays of each and took the difference between the two.

The analysis showed that the difference between the numbers of Λ_b and anti- Λ_b decays, divided by the sum of the two, differs by 2.45% from zero with an uncertainty of about 0.47%. Statistically speaking, the result differs from zero by 5.2 standard deviations, which is above the threshold required to claim an observation of the existence of CP violation in this baryon decay.

While it has long been expected that CP violation exists among baryons, the complex predictions of the Standard Model of particle physics are not yet precise enough to enable a thorough comparison between theory and the LHCb measurement.

Perplexingly, the amount of CP violation predicted by the Standard Model is many orders of magnitude too small to account for the matter–antimatter asymmetry observed in the Universe. This suggests the existence of new sources of CP violation beyond those predicted by the Standard Model, the search for which is an important part of the LHC physics programme and will continue at future colliders that may succeed it.

“The more systems in which we observe CP violations and the more precise the measurements are, the more opportunities we have to test the Standard Model and to look for physics beyond it,” says Vagnoni. “The first ever observation of CP violation in a baryon decay paves the way for further theoretical and experimental investigations of the nature of CP violation, potentially offering new constraints for physics beyond the Standard Model.”

“I congratulate the LHCb collaboration on this exciting result. It again underlines the scientific potential of the LHC and its experiments, offering a new tool with which to explore the matter–antimatter asymmetry in the Universe,” says CERN Director for Research and Computing, Joachim Mnich.

A trailblazer at 90

Find out how CERN is celebrating the 90th birthday of medical physics pioneer Ugo Amaldi and how you can be involved

(Image: Ugo Amaldi)

Join CERN on **Friday, 4 April** to celebrate the achievements and long career of Ugo Amaldi as he turns 90.

Ugo Amaldi joined CERN as a fellow in September 1961. He then spent 10 years at the Italian health institute *Istituto Superiore di Sanità* in Rome, performing experiments in nuclear and particle physics alongside radiation physics and radiotherapy. Returning to CERN, he helped to discover the rise in energy in the proton–proton cross-section at the [Intersecting Storage Rings](#), and later led the [DELPHI](#) collaboration at the [Large Electron–Positron Collider](#) (LEP). In the early 1990s, he founded the TERA Foundation, introducing hadron therapy to Italy. Today, he

continues to promote the use of accelerators in cancer treatment and is president emeritus of the National Centre for Oncological Hadrontherapy (CNAO) in Pavia.

Hear all about his outstanding contributions to physics and society on **Friday, 4 April, from 2 p.m. in the Main Auditorium**. Distinguished scientists will present and discuss his major achievements, including his contributions to particle physics while at CERN, the creation of the TERA Foundation, the design of novel particle accelerators for hadron therapy and his role in setting up an international network for cancer treatment with proton and ion beams. The celebrations will then continue with a drinks reception.

[Register now](#) to attend in person. The event is open to all, but registration is required for organisational purposes and to issue CERN access cards for non-CERN attendees. A [webcast](#) will also be available for the event.

Read more in an [interview with Ugo Amaldi in the latest CERN Courier](#) that draws on his childhood memories and his distinguished career at CERN to offer deeply personal insights into his father Edoardo's foundational contributions to international cooperation in science. See also his contribution to the CERN70 feature series: [From physics to medicine](#).

CERN announces winner of third Collide Copenhagen residency

Martyna Marciniak wins the third edition of the Collide Copenhagen residency organised by Arts at CERN in partnership with Copenhagen Contemporary

Portrait of Martyna Marciniak (Image: CERN / Copenhagen Contemporary)

Following an international open call launched in collaboration with [Copenhagen Contemporary](#) in November, [Arts at CERN](#) has announced that Polish artist Martyna Marciniak has won the third edition of the Collide Copenhagen residency.

[Collide](#) is a residency programme organised by Arts at CERN in partnership with a leading cultural institution in a CERN Member State. Established in 2012, the residency offers artists a unique opportunity to immerse themselves in the Laboratory's environment and engage in meaningful dialogue with its scientific community. The thirteenth edition of Collide, and the third of Collide Copenhagen, attracted 774 proposals from 109 different countries.

Martyna Marciniak is a Polish artist and researcher based in Berlin. Her interdisciplinary practice combines spatial storytelling, speculative fiction and 3D reconstruction to examine how design and technology shape ideologies and social structures. Her recent work has focused on developing a methodology that integrates the aesthetics of disinformation into a semi-fictional storytelling format that ignites imagination and critical reflection.

Marciniak will complete a two-month residency, split between CERN and Copenhagen Contemporary, to develop her proposal, entitled "2.2 microseconds: an anomaly". The project investigates the "split-second problem", examining how micro-temporal events, such as a

muon's 2.2-microsecond lifespan, reveal the interconnectedness of human systems and cosmic phenomena. One such anomaly is the bit-flip, where cosmic rays alter a bit in a computer's memory. These glitches expose the inner workings of technological, financial and computational infrastructures, paradoxically rendering them more perceptible.

The artist will create a sculptural timepiece and a video essay that explore the intersections between cosmic, technological and bodily timescales. Drawing from muon tomography and scientific timekeeping, the sculpture will reflect the infrastructures designed to measure fleeting phenomena. The video essay will propose new narratives and sensory modes for experiencing time's complexity, inviting a sense of wonder about the errors that shape our world.

"At Copenhagen Contemporary, we are beyond excited to round up a successful three-year partnership with Arts at CERN by presenting Martyna Marciniak as the third recipient of Collide Copenhagen. Marciniak's project for Collide seeks to modulate our understanding of time, offering new narratives and sensory modes for experiencing its complexity," says Marie Laurberg, director of Copenhagen Contemporary.

Together with the 2023 and 2024 awardees, Joan Heemskerk and Alice Bucknell, Marciniak will take part in the exhibition "Soft Robots", which will open in June at Copenhagen Contemporary.

The jury consisted of Giulia Bini, head of programme and curator of "Enter the Hyper-Scientific" at EPFL Lausanne; Vitor Cardoso, director of the Centre of Gravity at the Niels Bohr Institute; Marie Laurberg, director of Copenhagen Contemporary; Majken Overgaard, an independent curator, and Ana Prendes, assistant curator of Arts at CERN.

Collide Copenhagen has been the collaboration framework between CERN and Copenhagen Contemporary since 2023, as part of a three-year collaboration. A new partner for the Arts at CERN residency programme will be announced in 2025.

Computer Security: The cost of compromise

Recently, the Computer Security Office [reported on a cybersecurity incident](#) at a remote Tier 2 site of the Worldwide LHC Computing Grid (WLCG). Compromised to the backbone, dozens of servers deeply infiltrated by the attackers, taken over and abused for cryptocurrency mining. For months. While the attackers' earnings in dollars might reach five digits, the costs to that Tier 2 site are also significant. Let's look at the ledger:

- Instead of performing physics computing, some nodes were mining cryptocurrency. This implies Tier-2-sponsored electricity being converted into Bitcoin and pocketed by the attackers. And computing resources were blocked from doing physics analysis.
- Since the detection in October 2024, the site has been taken offline. Hence, with their compute nodes down for four months now, this equates to about 5% of the investment in their computing power (assuming a hardware lifetime of eight years).
- On top of that comes the cost of reputational damage due to bad publicity and criticism in the media.
- The whole sysadmin team has since been occupied with incident response, delaying any software development. A team of five people occupied for four months results in twenty months of personpower (PM) in salaries paid for nothing productive. In addition, the CERN Computer Security Office

has invested about 0.5 PM in recent months to help out with guidance, forensics and consultancy.

- Re-establishing full functionality will take even more time and resources and will require money for external consultancy, reviews and possibly training to avoid it happening again.

Given that we cannot disclose the local currency and the average salaries, of course, we cannot share a quantitative figure. But in abstract numbers over the whole time span of 6–8 months (detection, response and reinstallation) this adds up to 30–40 PM and 10% of their investment in compute. Or 10% of their committed computing power. Either number is non-negligible.

Compare that with the costs of implementing proper security measures prior to any incident. Actually, "prior" doesn't even matter anymore as the same security measures will definitely need to be implemented in the aftermath. Any auditor, any incident responder and, in this particular case, even the attackers(!) pushed for such proper measures. And with 40 PM and 10% of the operating expenses of a computer centre, you can already put some decent security mechanisms in place. Firewalls. Monitoring. Better configurations. So, what about you? Ready to act prior to or after an incident?

Computer Security Office

Official News

Members of the personnel shall be deemed to have taken note of official news published for the CERN community. Reproduction of all or part of this information by persons or institutions external to the Organization requires the prior approval of the CERN Management. The full list of official news is available here: <https://cern.ch/official-news>.

REMINDER: Laser pointers banned in Switzerland

A "laser pointer" is a small, hand-held laser device that emits laser radiation to indicate objects and locations.

From 1 June 2019, **only class 1 laser pointers** will be allowed for display purposes in Switzerland: **it is forbidden to import, possess and use laser pointers of classes 1M, 2, 2M, 3R, 3B and 4**, as

well as unclassified or incorrectly labelled laser pointers (Articles 22 and 23 of the Ordinance to the Federal Law on Protection against Non-ionising Radiation and Sound (NISRV)).

All CERN contributors must comply with these regulations. Failure to do so may result in criminal prosecution in Switzerland.

To avoid any incidents related to the use of laser pointers, their use is also restricted to class 1 equipment throughout the CERN site, including the French part.

Laser pointers must be disposed of as electronic waste after removing the batteries.

If you are in possession of a laser pointer of class 1M or higher, you can return it for proper disposal by placing it in one of the blue containers reserved for electronic equipment provided by the Storage, Recovery and Sales Service of the SCE department or return it directly to building 133.

The CERN Fire and Rescue Service launches the “Be ready, be safe!” campaign

Coming soon to a restaurant near you

Do you have questions about fire safety, emergency response or first aid?

The CERN Fire and Rescue Service is here to help!

Join us at our pop-up stands for interactive discussions, live demonstrations, hands-on experience with emergency equipment (e.g. fire extinguishers), and expert advice on:

- Fire safety at CERN and at home
- How to react in the event of an emergency
- Basic first-aid techniques
- Prevention

Two or three sessions will be held each month, rotating around CERN's three restaurants. For the full programme, see: <https://hse.cern/BeReadyBeSafe>. Pop by, get involved and be prepared!

And, if you haven't done so yet, why not complete your first-aid knowledge by attending the Life-Saving Actions training course? Find out more about course content and dates on the [CERN learning hub](https://hse.cern/BeReadyBeSafe).

HSE unit

Pedal Power: join CERN's 2025 Bike to Work Challenge!

The popular *Bike to Work* challenge is back for its 2025 edition. This Switzerland-wide initiative encourages us all to grab our handlebars throughout May and June. So, whether you're a cycling pro or a beginner, it's time for pedal power.

How to join:

1. **Form a team of four** and register on the [Bike to Work website](https://biketowork.ch). No team? No problem – you can request to join an incomplete one.
2. **Flexible rules:** No registration fee, no minimum distance, and part of your commute can include public transport. One teammate can even walk, skateboard or use any non-motorised transport.

In this edition, CERN is once again joining forces with the State of Geneva and more than 40 local entities, including Geneva municipalities, public organisations and other international institutions. Together, we'll make a bold statement promoting active mobility and well-being across Geneva. Winners will be rewarded with special prizes offered by participating organisations.

For more details and tips, check out the [Bike to Work FAQ](https://biketowork.ch) and [Bike to CERN](https://biketowork.ch) web pages. Stay safe by completing the [Road Traffic – Bike Riding](https://biketowork.ch) online course and reviewing CERN's [cycling safety tips](https://biketowork.ch). Let's hope for sunshine, safe roads and enjoyable cycling!

"La nuit est belle!" 2025

On 11 April, CERN will participate in the fifth edition of "La nuit est belle !", by switching off the lights of its premises all evening and night

On the evening of Friday, 11 April, CERN will participate in the fifth edition of ["La nuit est belle !"](#). The aim of this initiative is to make turning off or reducing the intensity of public lighting in the middle of the night commonplace.

The theme of the fifth edition is "The culture... of the night." The founding and organising partners chose this due to the power of culture to raise awareness and change practices.

CERN will join this initiative by switching off the lights all evening and night, of the Globe, the Science Gateway Portal, Gate E, the roads and car parks on the Meyrin and Prévessin sites, and the SPS and LHC sites, except where lighting is required for safety reasons.

If you are working at CERN, you can contribute by **switching off your computers, monitors and lights when you go home**. Please remember that switching off computers and lights is good practice

in general to save energy and favour biodiversity at night, read more at <https://hse.cern/content/energy-management>.

During the evening and over the weekend, many activities will be organised in the local area. Visit <https://lanuittestbelle.org> for more information and to register for activities. You can also follow the event live on social media via the hashtag [#lanuittestbelle](#).

Cyclists and pedestrians – make sure that you can be seen in the dark! Car-drivers – stay alert!

HSE recommends that you wear light-coloured clothing, [preferably with reflectors](#), if you are out when it is dark.

- People wearing dark clothes will be seen by a car from a distance of about 25 metres
- People wearing light-coloured clothes will be seen from a distance of about 40 metres
- People wearing reflectors will be seen from a distance of about 125 metres

Spring is here, and so are the ticks!

A guide to ticks, risks and prevention, to help you enjoy the great outdoors safely

Spring has arrived and the lure of the great outdoors grows as the days get longer and warmer. This also means the return of ticks: little parasitic mites, whose bites can have severe consequences for our health through the transmission of various infectious agents. The most common infections caused by tick bites are [Lyme disease](#) (Lyme Borreliosis), generally treatable with antibiotics, and [tick-borne encephalitis](#) (TBE), which is rarer than Lyme disease with 5000 to 13 000 cases reported globally each year. Although there is no vaccine against Lyme disease, one does exist against TBE and it is recommended for anyone, including children residing in or travelling to areas where the

disease is prevalent. In Europe, the TBE vaccination is recommended in Switzerland as well as Austria, Czech Republic, Estonia, Finland, Germany, Latvia, Lithuania, Poland, Slovakia, Slovenia, Sweden and Western Russia.

If you are bitten by a tick, you can go to the CERN Medical Service [infirmary](#) to have it removed and to get advice and guidance.

Find out more about ticks and tick-borne diseases, vaccination possibilities, how to protect yourself and what to do if you are bitten by a tick on the dedicated Medical Service webpage: <https://hse.cern/ticks>.

Medical Service

The power of mediation

Mediation in the workplace has many advantages, in both the short and the long term.

Conflict is a natural and inevitable part of working life. A conflict may seem trivial and unimportant at first but, over time, a “blame game” can develop, with each party making accusations about the other. The conflict is starting to escalate.

When conflict situations are brought to my attention, I offer a safe space where people can express themselves without feeling judged. This is essential to enable the people who consult me to unburden themselves and take a step back from what is happening and the impact it is having. I listen carefully and sympathetically to my visitors and, to help clarify the situation, I ask questions such as: “How did the conflict start?”, “How is this situation affecting you?”, “What have you already tried to do about it?”, “What do you need most to be able to improve the situation?”, etc.

I recall with great satisfaction a comment that one person made at the end of our conversation: “Thank you, I can see more clearly now. I have a plan.” My visitor had regained some control over the situation and could see a path to a possible solution.

In cases where the conflict has escalated sharply and communication has completely broken down, the people involved may feel isolated and may even deliberately distance themselves from others, with a growing sense of insecurity. Here, again, it is important that I provide clarity and reassurance.

I then guide the person towards a solution that enables them to approach the conflict situation more calmly and assertively. With my visitors' express permission, I can also contact their line management or colleagues myself, or put them in touch with other relevant services within the Organization.

Finally, parties who are in conflict and wish to move towards a resolution can request mediation.

After studying the request, I make sure that the parties involved are sincerely committed to the mediation and want it to succeed, explain how the facilitation day will unfold and set out the basic rules to be followed throughout the process (e.g. confidentiality, respect for each person's speaking time, non-violent communication and a focus on finding flexible solutions).

My role requires me to be sympathetic but neutral, i.e. free from judgement or bias. I prepare the participants for the mediation individually and then facilitate their discussions, helping them to seek practical solutions that meet their specific needs. This is not a negotiation, but a constructive exchange aimed at finding common ground in order to break the stalemate and move forward.

As one participant in a successful team mediation put it: “We're making a fresh start and we're going to work together as a team again.”

If you would like to talk about this subject or find out how the information above can be applied in a particular situation, please contact me. As Ombud, my main purpose is to provide a non-official channel for conflict resolution, as well as to give impartial help and advice. My role is also to offer my opinion on the implementation of the Code of Conduct.

Thank you for your attention, and I look forward to seeing you soon.

Marie-Luce Falipou

I would like to hear your reactions and suggestions – join the CERN Ombud Mattermost team at <https://mattermost.web.cern.ch/cern-ombud/>.

The Ombud is available from Monday to Friday in Office 500/1-004 on the Meyrin site. To make an appointment, in person or online, contact the Ombud at ombuds@cern.ch.

More information can be found on the Ombud's website: <https://ombuds.web.cern.ch/>
